Sativex® Oromucosal Spray

(delta-9-tetrahydrocannabinol and cannabidiol)

Warnings and precautions

Page 2

Talk to your doctor or pharmacist before using Sativex:

- If you are pregnant or plan to become pregnant.

Do not use Sativex:

- If you are allergic to cannabis extracts or any of the other ingredients of this medicine (listed in section 6).
- If you or anyone directly related to you has any mental health problems such as schizophrenia, psychosis or other significant psychiatric disorder. This does not include depression due to your multiple sclerosis.
- If you are breast-feeding.

Page 2

Pregnancy, breast-feeding and contraception (men and women)

Page 3

- If you are pregnant or breast-feeding, think you may be pregnant or are planning to have a baby, ask your doctor or pharmacist for advice before using this medicine.
- Do not use Sativex during pregnancy, unless advised to by your doctor.
- Whether male or female you must use a reliable contraceptive method while using this medicine. Keep using it for at least 3 months after your treatment has stopped.
- Do not use Sativex while breast-feeding.

HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use EPIDIOLEX® safely and effectively. See full prescribing information for EPIDIOLEX.

EPIDIOLEX® (cannabidiol) oral solution, CX [pending DEA scheduling action]

Initial U.S. Approval: XXXX [pending controlled substance scheduling]

----------INDICATIONS AND USAGE----------

EPIDIOLEX is indicated for the treatment of seizures associated with Lennox-Gastaut syndrome or Dravet syndrome in patients 2 years of age and older (1)

----------ADVERSE REACTIONS----------

The most common adverse reactions (10% or more for EPIDIOLEX and greater than placebo) are: somnolence; decreased appetite; diarrhea; transaminase elevations; fatigue, malaise, and asthenia; rash; insomnia, sleep disorder, and poor quality sleep; and infections. (6.1).

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

There are no adequate data on the developmental risks associated with the use of EPIDIOLEX in pregnant women. Administration of cannabidiol to pregnant animals produced evidence of developmental toxicity (increased embryofetal mortality in rats and decreased fetal body weights in rabbits; decreased growth, delayed sexual maturation, long-term neurobehavioral changes, and adverse effects on the reproductive system in rat offspring) at maternal plasma exposures similar to (rabbit) or greater than (rat) that in humans at therapeutic doses *(see Animal Data)*. In the U.S. general population, the estimated background risk of

Oral administration of cannabidiol (0, 50, 80, or 125 mg/kg/day) to pregnant rabbits throughout organogenesis resulted in decreased fetal body weights and increased fetal structural variations at the highest dose tested, which was also associated with maternal toxicity. Maternal plasma cannabidiol exposures at the no-effect level for embryofetal developmental toxicity in rabbits were less than that in humans at the RHD.

Cannabinoids and Mitochondria

Early Studies

Abstract

Delta9-Tetrahydrocannabinol (delta9-THC), the active ingredient of marihuana was found to be a highly effective inhibitor in vitro of the NADH-oxidase activity of rat brain and heart mitochondria. The degree of inhibition of the enzyme system obtained from rat brain tissue varied with the region from which it was derived as follows, in the presence of 10(-5) M delta9-THC: hypothalamus plus thalamus plus midbrain, 73 +/- 4%; cerebellum, 66 +/- 4%; medulla oblongata plus pons, 63 +/- 6%; cerebral cortex, 50 +/- 8%. The same concentration inhibited rat heart NADH-oxidase activity 69 +/- 9%. Inhibition of NADH-oxidase activity by a corresponding concentration of deoxycorticosterone was significantly less in all tissue preparations tested, ranging from 11% to 26%. The inhibition of delta9-THC appeared to be competitive and near the amytal-sensitive site of the electron transport system. Suggestive evidence was also obtained for a second site of action, above the cytochrome c site.

Classical views posit G protein-coupled cannabinoid receptor 1s (CB1Rs) at the cell surface with cytosolic Giα-mediated signal transduction. Hebert-Chatelain et al. (2016) instead place CB_1Rs at mitochondria limiting neuronal respiration by soluble adenylyl cyclase-dependent modulation of complex I activity. Thus, neuronal bioenergetics link to synaptic plasticity and, globally, learning and memory

Cannabinoid Decline with age Mimics that Occurring with Age

Tubulin, Actin, RNA

Tubulin

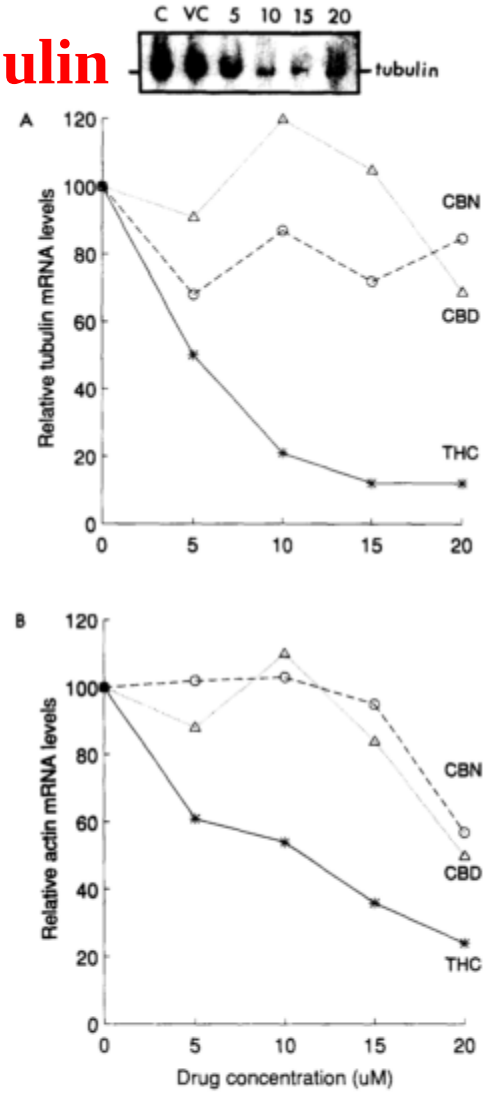

FIG. 3. Northern blot hybridization analysis of tubulin and actin mRNA levels in THC, CBD or CBN treated CHO cells for 2 h. Total RNA was phenol extracted from cells following treatment. A 10 μg aliquot of total RNA from each sample was fractionated by electrophoresis on a 1.5% agarose-6% formaldehyde gel, transferred to nitrocellulose and hybridized with a ^{32}P nick-translated tubulin (PT25) or actin (PA72) cDNA probe. Autoradiograms were analyzed by densitometry and the relative intensity of mRNA levels were determined and expressed relative to untreated controls. There was no difference in tubulin or actin mRNA levels between untreated and vehicle controls. The insert shows a representative autoradiogram of the region where the PT25 clone hybridized to the nitrocellulose filter. (A) Relative tubulin mRNA levels; (B) Relative actin mRNA levels.

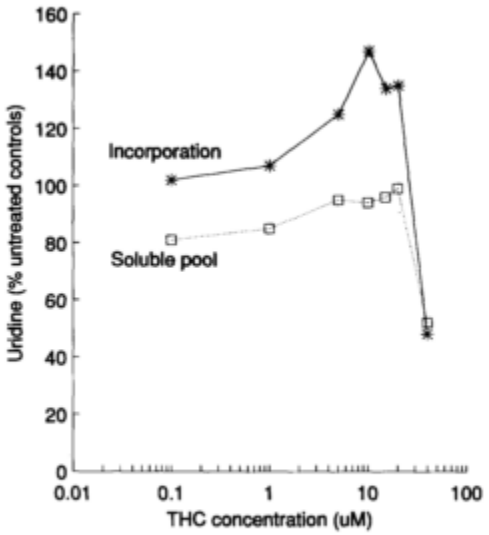

FIG. 4. Influence of THC on the incorporation of ^{3}H uridine into RNA. CHO cells grown in monolayer were pulsed during the last hour of drug treatment with 5 μCi/ml ^{3}H uridine. The incorporation of radioactivity into the acid-insoluble fraction was determined. The acid-soluble uridine fraction was estimated by subtracting the acid-insoluble fraction from the total cellular uptake of uridine for cells treated between 0.1 and 40 μM THC for 2 h. Data is expressed as a percentage of untreated controls. The vehicle had no effect on the incorporation of uridine as compared to untreated controls.

was a change in the cytoskeletal architecture and the mRNA levels of cytoskeletal proteins (tubulin and actin) in CHO cells following THC but not CBD or CBN treatment at concentrations which did not adversely affect cell proliferation. Stress fibers were reduced in number and length, and microtubules became fragmented in CHO cells treated with 10 μM THC for 2 h. Moreover, the levels of tubulin and actin mRNA transcripts were reduced.

The mechanism(s) by which THC alters the cytoskeletal architecture is unknown. THC may interact directly with the cytoskeletal elements or interfere with the process of assembly and disassembly. Preliminary reports have shown that THC influenced the in vitro assembly and disassembly of tubulin (40). THC may also affect the cytoskeleton indirectly by its effects on other cellular structures or other biochemical activities. Since the cytoskeleton is closely associated with cell membranes, THC interaction with the lipid bilayer or membrane bound enzyme systems, may adversely influence the cytoskeletal architecture. THC may also affect the permeability of the membrane to ions such as Ca^{2+}, an ion known to inhibit microtubule polymerization and disrupt actin microfilament assembly (37). THC may influence the organization of the cytoskeleton by affecting biochemical events involved in gene regulation. In our studies, the reduction in tubulin and actin mRNA levels may reflect cannabinoid-mediated effects on mRNA transcription, stability or processing of mRNA transcripts. Thus further studies on the cytoarchitecture and the expression of cytoskeletal proteins will be useful in assessing the effects of cannabinoids at the cellular and molecular levels.

Human Study

MICROTUBULE DISRUPTION

Abstract

Children exposed in utero to cannabis suffer perpetual neurobehavioral and cognitive impairments. Psychoactive constituents from *Cannabis* spp., particularly Δ^9-tetrahydrocannabinol (THC), bind to cannabinoid receptors in the fetal brain. However, it is unknown whether THC can trigger a cannabinoid receptor-driven molecular cascade to disrupt neurodevelopmental specification. Here, we show that repeated THC exposure dysregulates cannabinoid signaling, particularly the temporal dynamics of CB_1 cannabinoid receptor, to rewire the fetal cortical circuitry. By interrogating the THC-sensitive neuronal proteome we identify Superior Cervical Ganglion 10 (SCG10)/stathmin-2, a microtubule-binding protein in axons, as a substrate of altered neuronal connectivity. We find SCG10 mRNA and protein reduced in the hippocampus of midgestational human cannabis-exposed fetuses, defining SCG10 as the first cannabis-driven molecular effector in the developing cerebrum. CB_1 cannabinoid receptor activation recruits c-Jun N-terminal kinases to phosphorylate SCG10, promoting its rapid degradation *in situ* in motile axons and microtubule stabilization. Thus, THC enables ectopic formation of filopodia and alters axon morphology. These data highlight the maintenance of cytoskeletal dynamics as a molecular target for cannabis, whose imbalance can limit the computational power of neuronal circuitries in affected offspring.

Introduction

The recreational use of cannabis use continu with adolescents and young adults being prin (Substance Abuse & Mental Health Service Administ Cannabis exposure of infants *in utero* or cannabis us (pregnant 15-17 years of age) (Substance Abuse & Service Administration, 2013) can coincide with crit in the developing brain when neuronal connectivity is pre lished (Kostovic & Jovanov-Milosevic, 2006) or postn to increase modularity and integrative capacity (Denn Accordingly, prospective longitudinal assessments *et al*, 2004; Willford *et al*, 2010; Day *et al*, 2011) cannabis use during pregnancy can increase the behaviors (Goldschmidt *et al*, 2004; Day *et al*, 2011), c (Huizink & Mulder, 2006), drug seeking (Day *et al*, 20 deficit (Leech *et al*, 1999), and anxiety and depressio 2006) among affected neonatal or adolescent offsprin population analysis associates growth retardation cannabis use (El Marroun *et al*, 2009), particularly sin efficient cross-placental transfer of Δ^9-tetrahydrocann (Grotenhermen, 2003), the major psychoactive *Cannabis* spp. Nevertheless, a gap of knowledge ex the neuronal basis of cannabis-induced developmen the nervous system.

Prenatal Cannabis Exposure (PCE) Is linked with:

- "Only a small minority of women (<35%) are forthcoming about their cannabis use
- Women who use cannabis during pregnancy are more likely to be younger, unmarried, of lower socioeconomic status (lower education and income), and to have had unplanned pregnancies, compared to pregnant women who don't use cannabis
- Effects of PCE are dose dependent with more severe negative effects occurring with heavier prenatal exposure
- PCE is associated with:
  - Lower birth weight
  - Shorter birth length
  - Lifelong smaller head circumference
  - Reduced length gestation
  - ***Neonatal neurological disturbances***
  - ***Reduced function in specific cognitive domains:***
  - ***In Grade school***
  - ***Increased impulsivity and***
  - ***Hyperactivity and***
  - ***Depression at age 10***
  - ***Poor school achievement***
  - ***Delinquency in adolescence***
  - ***Increase adolescent use of***
    - ***Tobacco and***
    - ***Cannabis***
  - ***Altered neural function for visuo-spatial memory and***
  - ***Motor impulse control in Early adulthood"***

CB1R's in Neural and Cortex Development

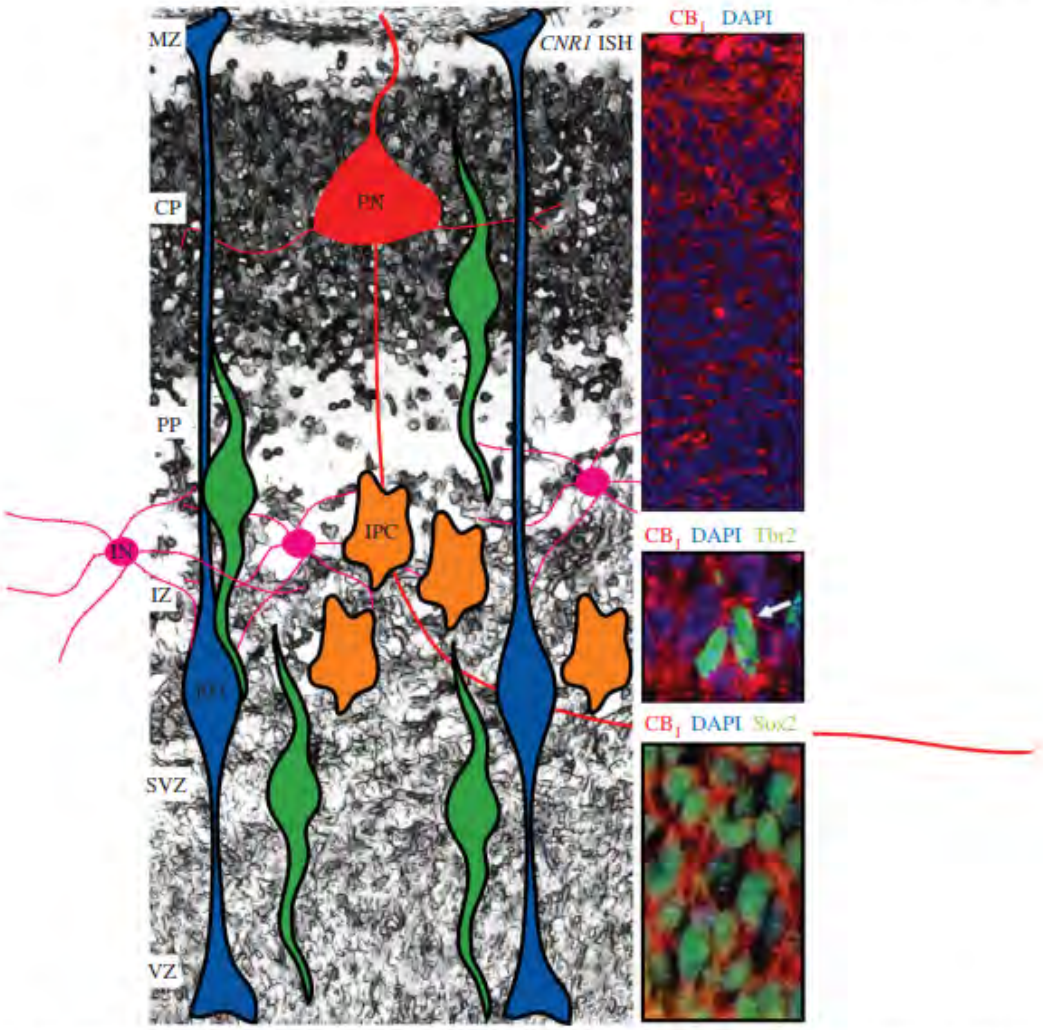

Figure 2. CB_1 cannabinoid receptor expression during cortical development. The CB_1 receptor is present in the developing cortex, showing increasing expression levels from undifferentiated to differentiated projection neurons (PNs). The CB_1 receptor is present in Cajal–Retzius cells of the marginal zone (MZ) and apical and basal progenitors in the ventricular and subventricular (VZ/SVZ) proliferative area. Representative immunofluorescence images showing the colocalization of the CB_1 receptor in radial glial (RG) progenitors and intermediate amplifying progenitor cells (IPCs) as identified with Sox2 and Tbr2 antibodies, respectively [13] (copyright National Academy of Sciences, USA 2009). Higher expression levels of the CB_1 receptor are evident in maturing neurons that have reached the CP, that correspond to locally generated PNs. CB_1 receptor is present in certain interneuron (IN) populations that reach the pallium upon tangential migration from the ganglionic eminences. Image background corresponds to a representative *in situ* hybridization of the *CNR1* mRNA at E.16.5 (by C. Hoffman and B. Lutz, Johannes Gutenberg University Mainz, Germany).

Endocannabinoids via CB_1 receptors act as neurogenic niche cues during cortical development.

Díaz-Alonso J[1], Guzmán M, Galve-Roperh I.

eCB's in Cortex Development

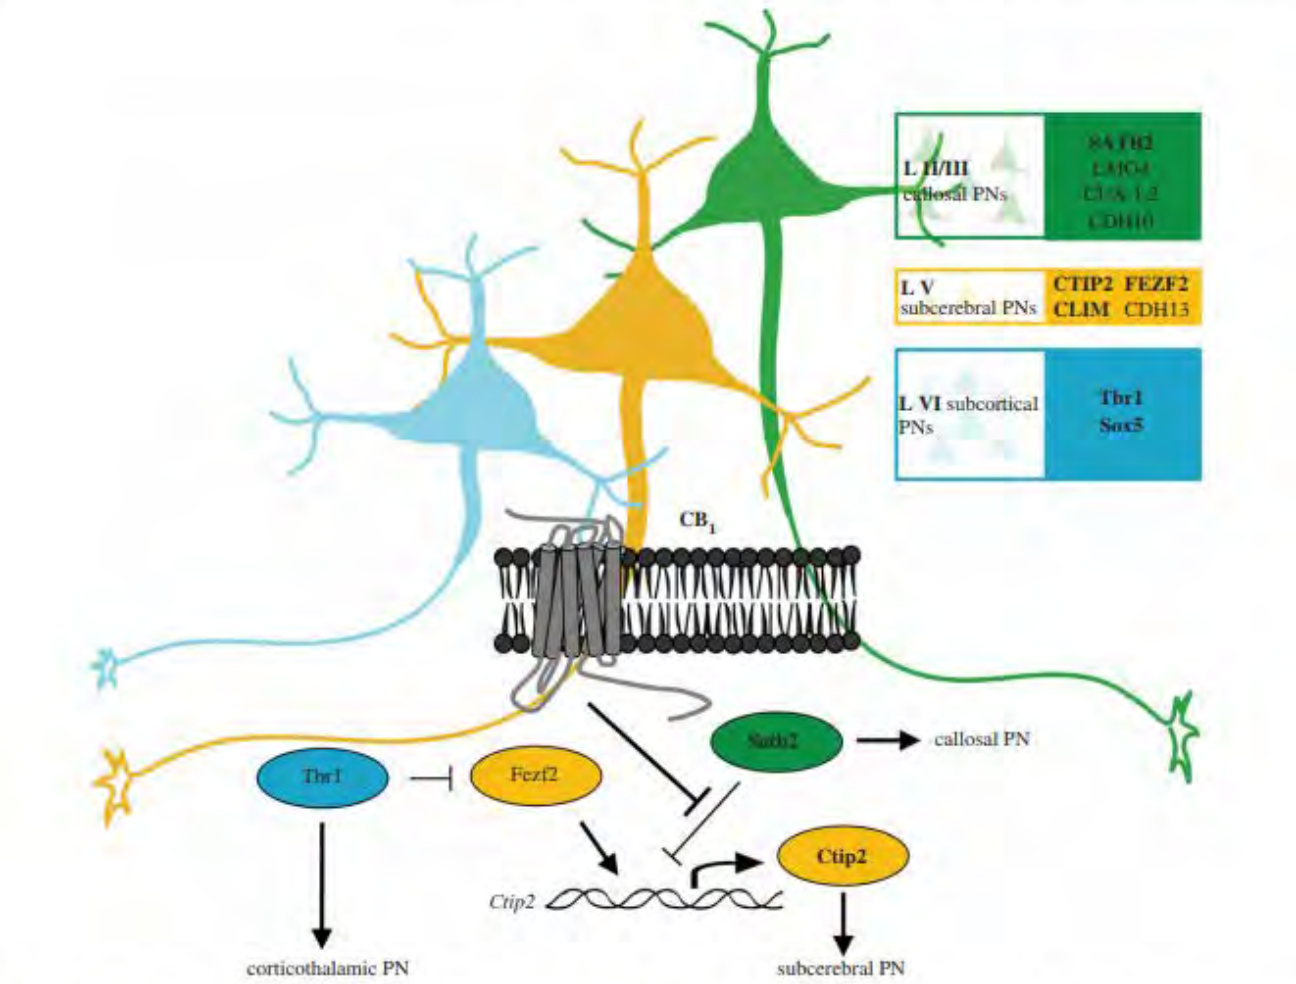

Figure 4. CB_1 cannabinoid receptor signalling and neuronal differentiation. CB_1 receptor activity in differentiating cortical neurons is coupled by as yet unknown mechanisms to the modulation of the neurogenic transcription factor code Ctip2-Satb2. CB_1 receptors are positively coupled to COUP-TF II interacting protein 2 (Ctip2) and negatively to Satb2-mediated repression of Ctip2. Thus, CB_1 receptor activity tunes the transcriptional neurogenic programme responsible for upper and lower cortical neuron differentiation. Transcription factors involved in cortical laminar specification regulated by CB_1 receptor are indicated in bold letters.

CB1R's Preferentially Expressed in Human Cord Blood iPSC's

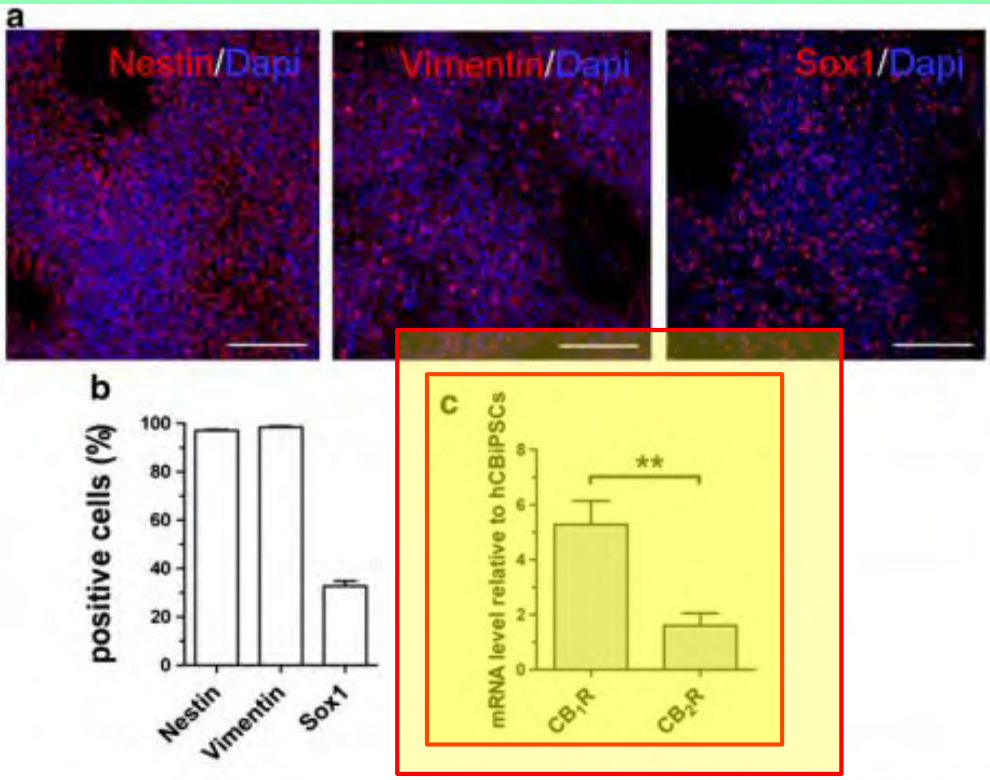

Figure 1 A homogeneous population of smNPCs derived from hCBiPSCs expressed CB_1R over CB_2R. (A + B) smNPCs uniformly expressed the neural progenitor markers nestin and vimentin and stained positive for Sox1 (33%). Nuclei were counterstained with Dapi. Bar graphs represent 50 µm. (C) qRT-PCR revealed significantly higher levels of the nervous system-specific CB_1R in smNPCs than CB_2R, which is more abundant in the immune system ($p = 0.0086$, Mann–Whitney test). Data are given relative to undifferentiated hCBiPSCs

Hi Dose CB's Reduce Brain Maturation iPSC NSC's Synaptic Currents

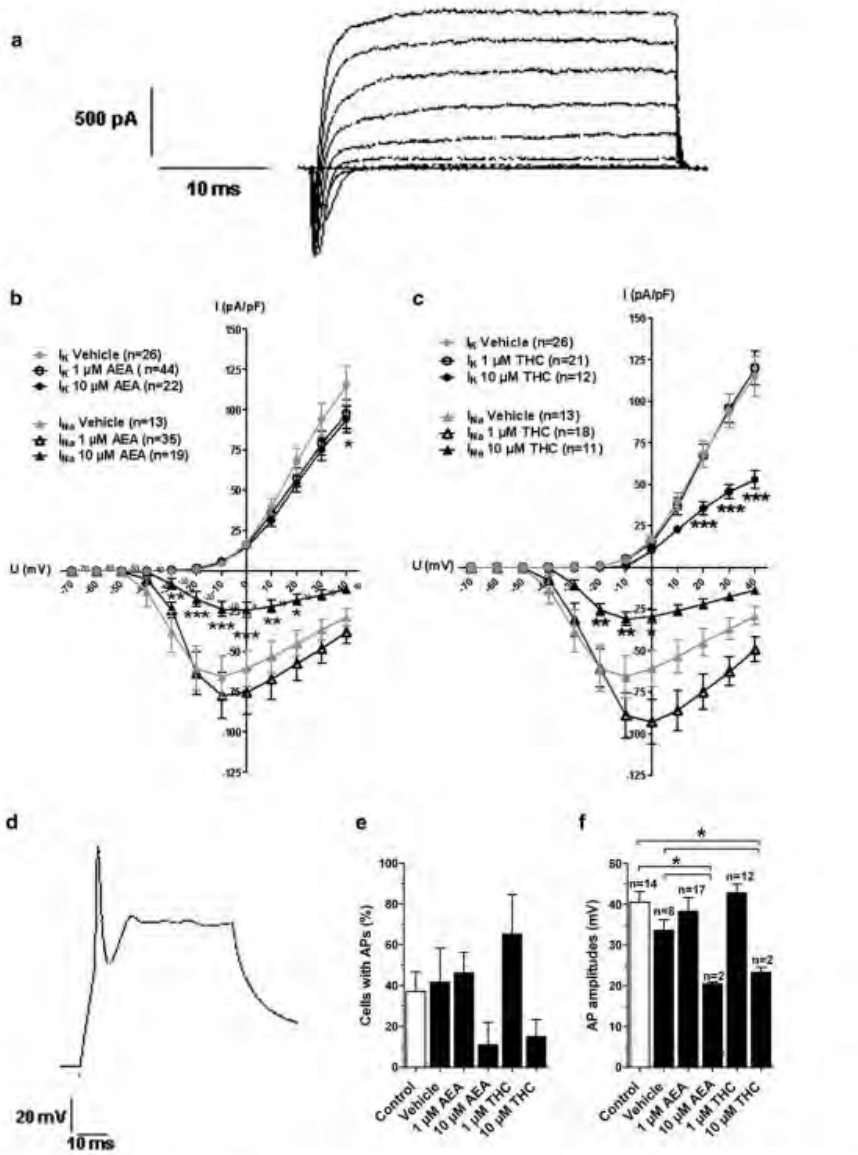

Figure 5 Treatment of differentiating smNPCs with higher dosages of CBs reduced voltage-gated ion currents and AP amplitudes. (A) Exemplary illustration of sodium inward (I_{Na}) and potassium outward currents (I_K) in smNPC-derived neurons after 21 days of differentiation. Current–voltage plots of neurons treated with 10-µM AEA (B) or 10-µM THC (C) showed significantly reduced I_{Na} and I_K compared to vehicle treated controls. Current amplitudes were normalized for cell capacitances and are plotted as means ± SEM. *P*-values were calculated using two-way ANOVA with Bonferroni post-test (***$p < 0.001$, **$p < 0.01$, *$p < 0.05$). (D) AP of a smNPC-derived neuron after 21 days of differentiation. (E) Under each condition a similar amount of around 40% of the cells fired APs. Only the cells that were incubated with 10-µM AEA or THC showed a tendency to lower percentages of cells with APs. (F) AP amplitudes were significantly reduced in cells co-incubated with 10-µM AEA or THC. Values were determined from three differentiation experiments as means ± SEM. *P*-values were determined using a Mann–Whitney test (*$p < 0.05$)

Hi dose CB's Alters iPSC NSC Synaptic Activity

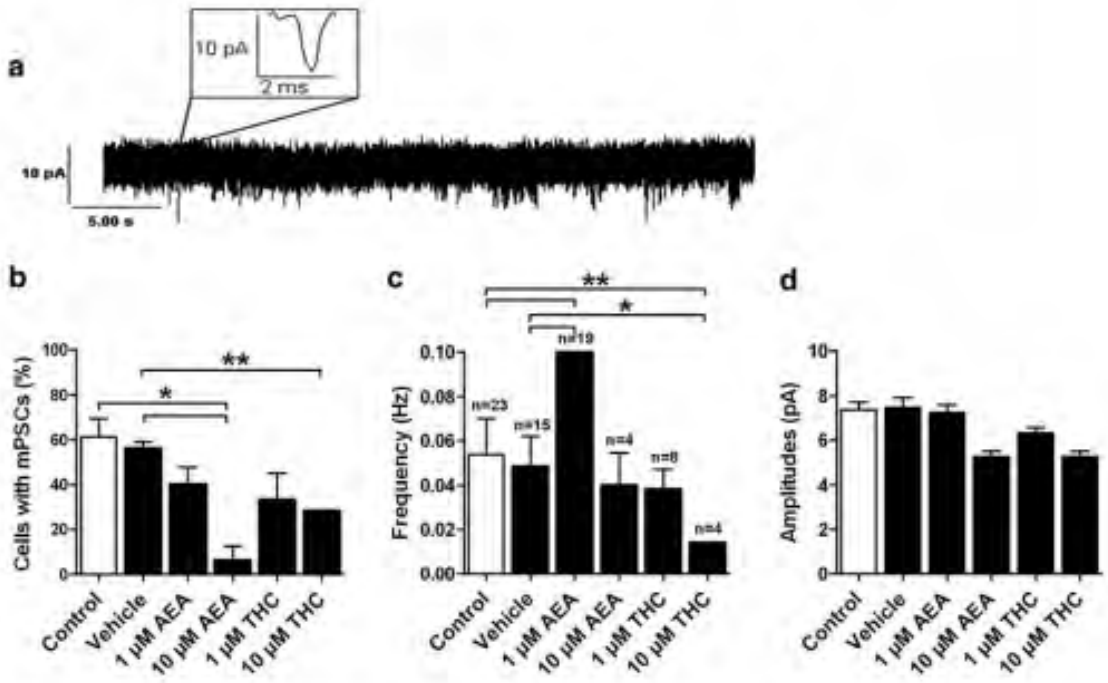

Figure 6 High concentrations of CBs reduced the percentage of smNPC-derived neurons with spontaneous synaptic activity while 1 µM AEA increased the frequency of synaptic currents. (A) Exemplary illustration of a current trace representing miniature spontaneous post-synaptic currents (mPSCs) recorded from a single cell after 21 days of differentiation. (B) The percentage of cells with mPSCs was significantly reduced by treatment with 10 µM AEA or THC. (C) Cells incubated with 1 µM AEA showed elevated current frequencies, while frequencies of cells differentiated in the presence of 10 µM THC were reduced. (D) No change in mPSC amplitudes was detected under the conditions tested. Data represent means ± SEM. *P*-values were calculated using a Mann–Whitney test (**$p < 0.01$, *$p < 0.05$)

Risk of Selected Birth Defects with Prenatal Illicit Drug Use, Hawaii, 1986–2002

Mathias B. Forrester and Ruth D. Merz
Hawaii Birth Defects Program, Honolulu, Hawaii, USA

The literature on the association between prenatal illicit drug use and birth defects is inconsistent. The objective of this study was to determine the risk of a variety of birth defects with prenatal illicit drug use. Data were derived from an active, population-based adverse pregnancy outcome registry. Cases were all infants and fetuses with any of 54 selected birth defects delivered during 1986–2002. The prenatal methamphetamine, cocaine, or marijuana use rates were calculated for each birth defect and compared to the prenatal use rates among all deliveries. Among all deliveries, the prenatal use rate was 0.52% for methamphetamine, 0.18% for cocaine, and 0.26% for marijuana. Methamphetamine rates were significantly higher than expected for 14 (26%) of the birth defects. Cocaine rates were significantly higher than expected for 13 (24%) of the birth defects. Marijuana rates were significantly higher than expected for 21 (39%) of the birth defects. Increased risk for the three drugs occurred predominantly among birth defects associated with the central nervous system, cardiovascular system, oral clefts, and limbs. There was also increased risk of marijuana use among a variety of birth defects associated with the gastrointestinal system. Prenatal uses of methamphetamine, cocaine, and marijuana are all associated with increased risk of a variety of birth defects. The affected birth defects are primarily associated with particular organ systems.

Attributable Fraction for Cardiac Malformations

P. David Wilson,[1] Christopher A. Loffredo,[1] Adolfo Correa-Villaseñor,[2] and Charlotte Ferencz[1]

To the authors' knowledge, attributable fractions for cardiac malformations have not been reported before. The Baltimore-Washington Infant Study published factors associated with several major cardiac malformations in Maryland, the District of Columbia, and adjacent counties of northern Virginia in 1981–1989. For eight of these malformations, the authors provide attributable fractions of those factors that are potentially causal. Summary attributable fractions range from 13.6% (four factors) for hypoplastic left heart to 30.2% (seven factors) for transposition of great arteries with intact ventricular septum. Extra attributable fraction for factor *x*, defined as summary attributable fraction for all factors minus that for all but *x*, is largest for: 1) paternal marijuana use in transposition of great arteries with intact ventricular septum, 7.8%; 2) paternal anesthesia in tetralogy of Fallot, 3.6%; 3) painting in atrioventricular septal defect with Down syndrome, 5.1%; 4) solvent/degreasing agent exposure in hypoplastic left heart, 4.6%; 5) sympathomimetics in coarctation of aorta, 5.8%; 6) pesticide exposure in isolated membranous ventricular septal defect, 5.5%; 7) hair dye in multiple/multiplex membranous ventricular septal defect, 3.3%; and 8) urinary tract infection in atrial septal defect, 6.4%. Percent-of-cases-exposed dominates relative risk in attributable fraction. If these factors are causal, the larger extra attributable fractions suggest the potential for prevention by specific interventions before/during pregnancy. *Am J Epidemiol* 1998;148:414–23.

[b]Grantley Stable Neonatal Unit, Royal Brisbane and Women's Hospital

Gastroschisis is a form of congenital anomaly which is characterised by an uncovered visceral herniation through a (typically) right side abdominal wall defect with an intact umbilical cord[1-3]. While omphalocele, another common form of abdominal wall defect, is often associated with other structural or chromosomal

Birth defects exceed NSW average

ONE in every 422 Lismore babies born between 2008 and 2010 had the horrific birth defect gastroschisis, a NSW Health report released yesterday shows.

The birth defect, in which babies are born with their intestinal contents protruding through the abdominal wall, affects about one baby in every 5000 to 10,000 live births.

The final report into a Northern Rivers cluster of gastroschisis – a condition in which babies are born with their intestinal contents freely protruding through a hole in the abdomen – has also revealed there were 26 cases of the rare condition over the past decade within an area extending from the Tweed to Port Macquarie.

Only 11 of these cases had been reported to NSW Register of Congenital Conditions, with 15 babies' details going unrecorded due do a breakdown in communication between NSW health authorities and the Brisbane hospital where the babies were transferred prior to birth for specialist treatment.

Gastroschisis:

Maternal Risk Factors for Gastroschisis in Canada

Erik D. Skarsgard*[1], Christopher Meaney[2], Kate Bassil[3], Mary Brindle[4], Laura Arbour[5], Rahim Moineddin[2], and the Canadian Pediatric Surgery Network (CAPSNet)

Background: Gastroschisis is a congenital abdominal wall defect that occurs in one per 2200 pregnancies. Birth defect surveillance in Canada has shown that the prevalence of gastroschisis has increased threefold over the past 10 years. The purpose of this study was to compare maternal exposures data from a national gastroschisis registry with pregnancy exposures from vital statistics to understand maternal risk factor associations with the occurrence of gastroschisis. **Methods:** Using common definitions, pregnancy cohorts were developed from two databases. The Canadian Pediatric Surgery Network database, a population-based dataset was used to record maternal exposures for women who experienced a gastroschisis pregnancy, while a contemporaneous, geographically cross-sectional "control" cohort of pregnant women and their exposures was developed from Canadian Community Health Survey data. Groups comparison of maternal risk factors was performed using univariate and multivariate logistic generalized estimating equation techniques. **Results:** A total of 692 gastroschisis pregnancies (from Canadian Pediatric Surgery Network) and 4708 pregnancies from Canadian Community Health Survey were compared. Younger maternal age (odds ratio, 0.85; 95% confidence interval, 0.83–0.87; $p < 0.0001$), smoking (odds ratio, 2.86; 95% confidence interval, 2.22–3.66; $p < 0.0001$), a history of pregestational or gestational diabetes (odds ratio, 2.81; 95% confidence interval, 1.42–5.5; $p = 0.0031$), and use of medication to treat depression (odds ratio, 4.4; 95% confidence interval, 1.38–11.8; $p = 0.011$) emerged as significant associations with gastroschisis pregnancies. **Conclusion:** Gastroschisis in Canada is associated with maternal risk factors, some of which are modifiable. Further studies into sociodemographic birth defect risk are necessary to allow targeted improvements in perinatal health service delivery and health policy.

Nunavut Cannabis

In that region, 84.6 per cent of men in Nunavik aged 15 to 19 admitted they used illegal drugs, mostly cannabis, during the 12 months prior to the date of the survey. For adult men up to the age of 45, self-reported numbers were similar, but dropped to 43.5 per cent after age 45.

Among girls and women in Nunavik, self-reported drug use, mostly cannabis, was lower: 69.3 per cent for girls aged 15 to 19 and falling to 49.6 per cent for women aged 25 to 44.

Cannabis regulation: Nunavut must take its time

"The GN must not feel bound by Ottawa's timetable"

NUNATSIAQ NEWS

Thanks to the two cannabis bills that Justin Trudeau's Liberal government unveiled this past April 13, the Government of Nunavut now faces some tough political choices.

That's because, if the Trudeau government's plan works out, Parliament will pass Bill C-45 and Bill C-46 in time for the new laws to take effect July 1, 2018, the date when Nunavut would be expected to do its part in carrying out Ottawa's agenda.

By then, territorial and provincial governments are supposed to decide, through regulations, how recreational cannabis products will be legally sold and distributed within their jurisdictions.

But July 2018, the Trudeau government wants to create a legalized cannabis system, subject to multiple restrictions, that r... territorial, provincial and municipal regulation. How sh... respond? (WIKIMEDIA FILE IMAGE)

NBDPN & NSDUH Publicly Available Data

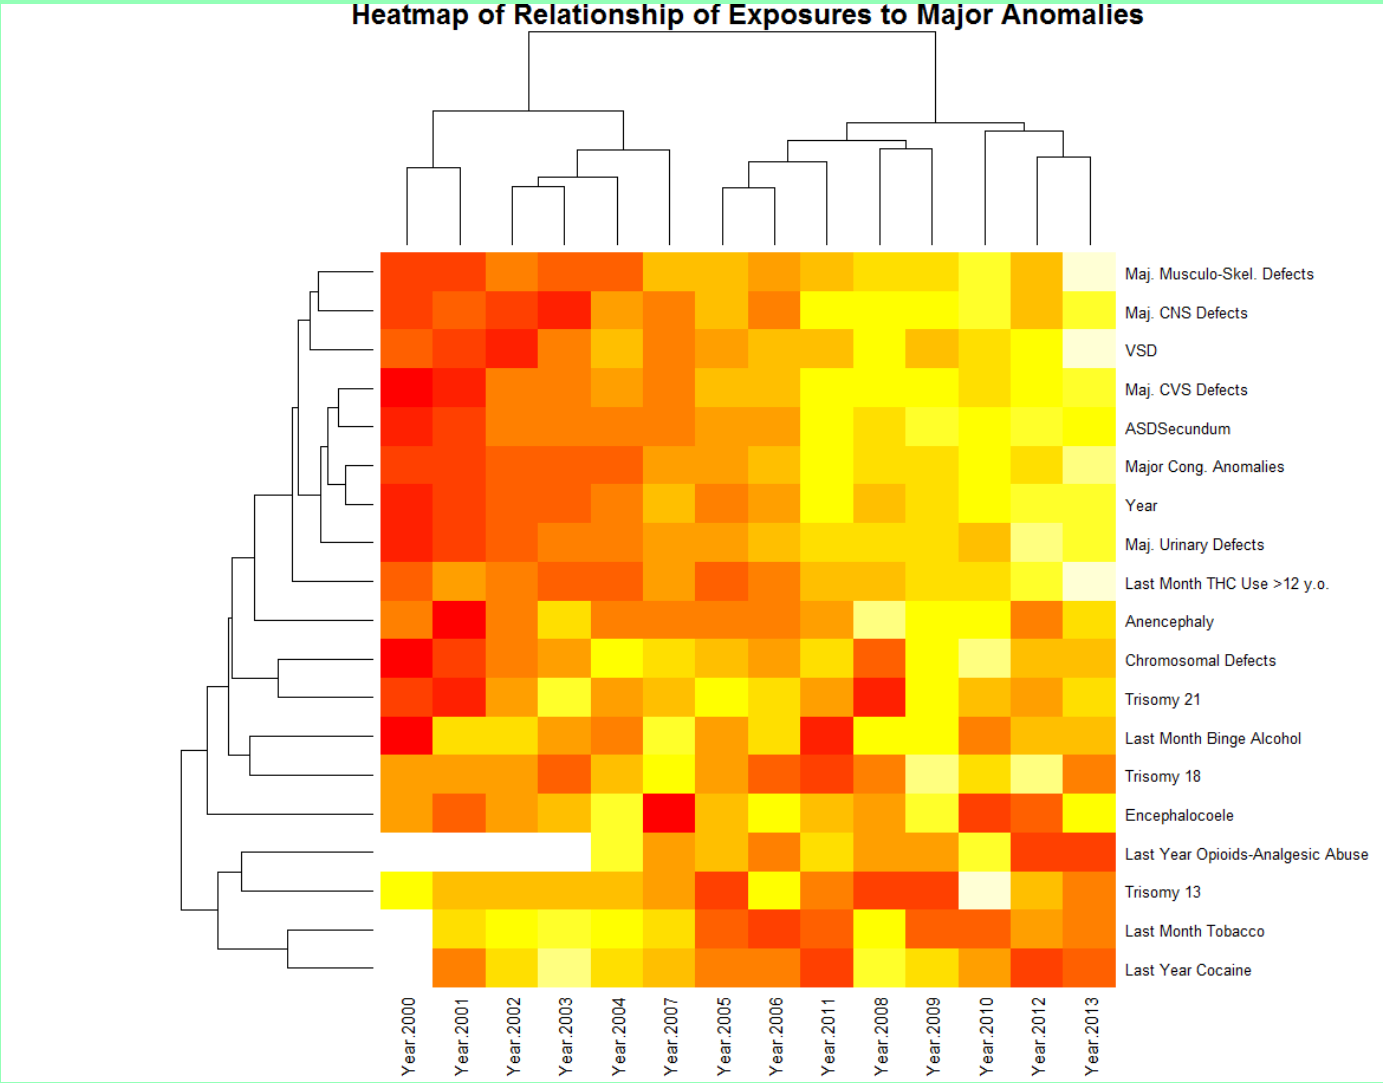
Heatmap – Selected Defect Clusters



CHILDREN

Congenital Defects Linked to Cannabis

- *Anencephaly – CDC / NBDPN, 2009, 2014*
- *Gastroschisis – CDC / NBDPN / Meta-analysis / Canada / NNSW – Frequency and Severity*
- *Diaphragmatic Hernia – CDC / NBDPN*
- *Oesophageal Stenosis ± Tracheal Fistula – CDC / NBDPN*
- *VSD – AHA / AAP / Colorado*
- *Ebsteins – AHA / AAP*
- *CVS Disorders – Colorado, AHA / AAP, Wilson 1998; Present*
- *ASD – Colorado Experience*
- *Chromosomal Defects – Forrest 2007 / Present USA analysis / Colorado / NNSW*
- *Brain Defects - Intelligence, Higher Cortical Functioning*
  - *First Principles – Stem Cells, Stem Cell Niche, NSC Wiring, Axon Guidance, Epigenetics, Immunity, Brain Inflammation*
  - *Vasculopathy – Large and small vessels*
  - *Longitudinal Studies OPPS, MHPCD, GenRStudy*
  - ***ANENCEPHALY***

Mechanisms of Cannabis Teratogenesis

- *Epigenetic*
- *Microtubule Disruption / Mitotic Spindle Toxicity / Indirect Genotoxin / Micronuclear formation / Chromosomal clastogens*
- *Mitonuclear Stress Signalling and Imbalance*
- *Secondary Effects of Low Cellular Energy Charge to DNA Maintenance*
- *Damage to Reproductive Tract*
- *Foetal Vasculopathy – CB1R / GPR55 / VR1 Mediated inflammation, vasospasm – Brain, Limbs, Abdomen*
- *Damage to VEGF / Stem Cell Niche*
- *Aging effect*
- *Mitochondrial Toxicity / Uncoupling / UCP2*
- *Carcinogenicity*
- *Non-linear kinetics*
- *Damage to Brain formation / Neuronal network formation to the point of Anencephaly*
- *Damage to Heart Formation – Endocardial Cushions – CB1R, GPR55*
- *Threshold Effect*

162 studies found for: tetrahydrocannabinol
Modify this search | How to Use Search Results

GW Pharmaceuticals major clinical trial sponsor

Comments:

Pain – many negative studies, a few positive
Lennox-Gestaut Syndrome Treatment Refractory Epilepsy
- Some positive studies, some negative
Dravet Syndrome Epilepsy – Positive Studies
MS – Several negative studies
Cancer – several negative studies
Long term Safety – 2.5 years –
No cancer, no foetal safety data, no statistical tests
Adverse Events data – no statistics
Tiny Size - 6 or 8 in treatment groups

Overall

- ***MANY NEGATIVE STUDIES***
- Many studies small,
- Low powered,
- Inadequately documented,
- Major design issues,
- No statistical comparisons

Dravet – No results posted; 3 trials Incl. Dose ranging & PK
Lennox Gestaut Synd not recruiting

European Registry:
Dravet - 4 Trials – No results available
Lennox-Gestaut - 3 Trials – No results available

Clinicaltrials.gov

Overall RCT Study Description

Study No.	CT No.	Drug	Short Description	N
28	NCT01606189	Sativex (THC/CBD) & THC	Pain - Nerve Injury - Arm	48
32	NCT01604265	Sativex (THC/CBD)	Pain - Neuropathic | Multiple Sclerosis	66
26	NCT00674609	Sativex (THC/CBD) & THC	Pain | Advanced Cancer	177
15	NCT00530764	Sativex (THC/CBD)	Pain | Advanced Cancer	360
20	NCT01606176	Sativex (THC/CBD)	Pain | Multiple Sclerosis	70
31	NCT01606202	THC/CBD	Pain - Nerve Injury - Spinal Cord	116
27	NCT00681538	Sativex (THC/CBD)	Multiple Sclerosis | Spasticity - **Selected**	241
23	NCT00702468	Sativex (THC/CBD)	Multiple Sclerosis | Spasticity - **Selected**	36
16	NCT01610700	Sativex (THC/CBD)	Multiple Sclerosis	160
25	NCT01599234	Sativex (THC/CBD)	Multiple Sclerosis	337
24	NCT00391079	Sativex (THC/CBD)	Multiple Sclerosis	339
19	NCT00678795	Sativex (THC/CBD)	Detrusor Overactivity | Multiple Sclerosis	124
33	NCT01964547	Sativex (THC/CBD)	Multiple Sclerosis | Spasticity	127
1	NCT01217112	CBD	Fatty Liver	25
3	NCT01284634	CBD	Dyslipidemias|Diabetes Mellitus, Type 2	62

CB1R Structure

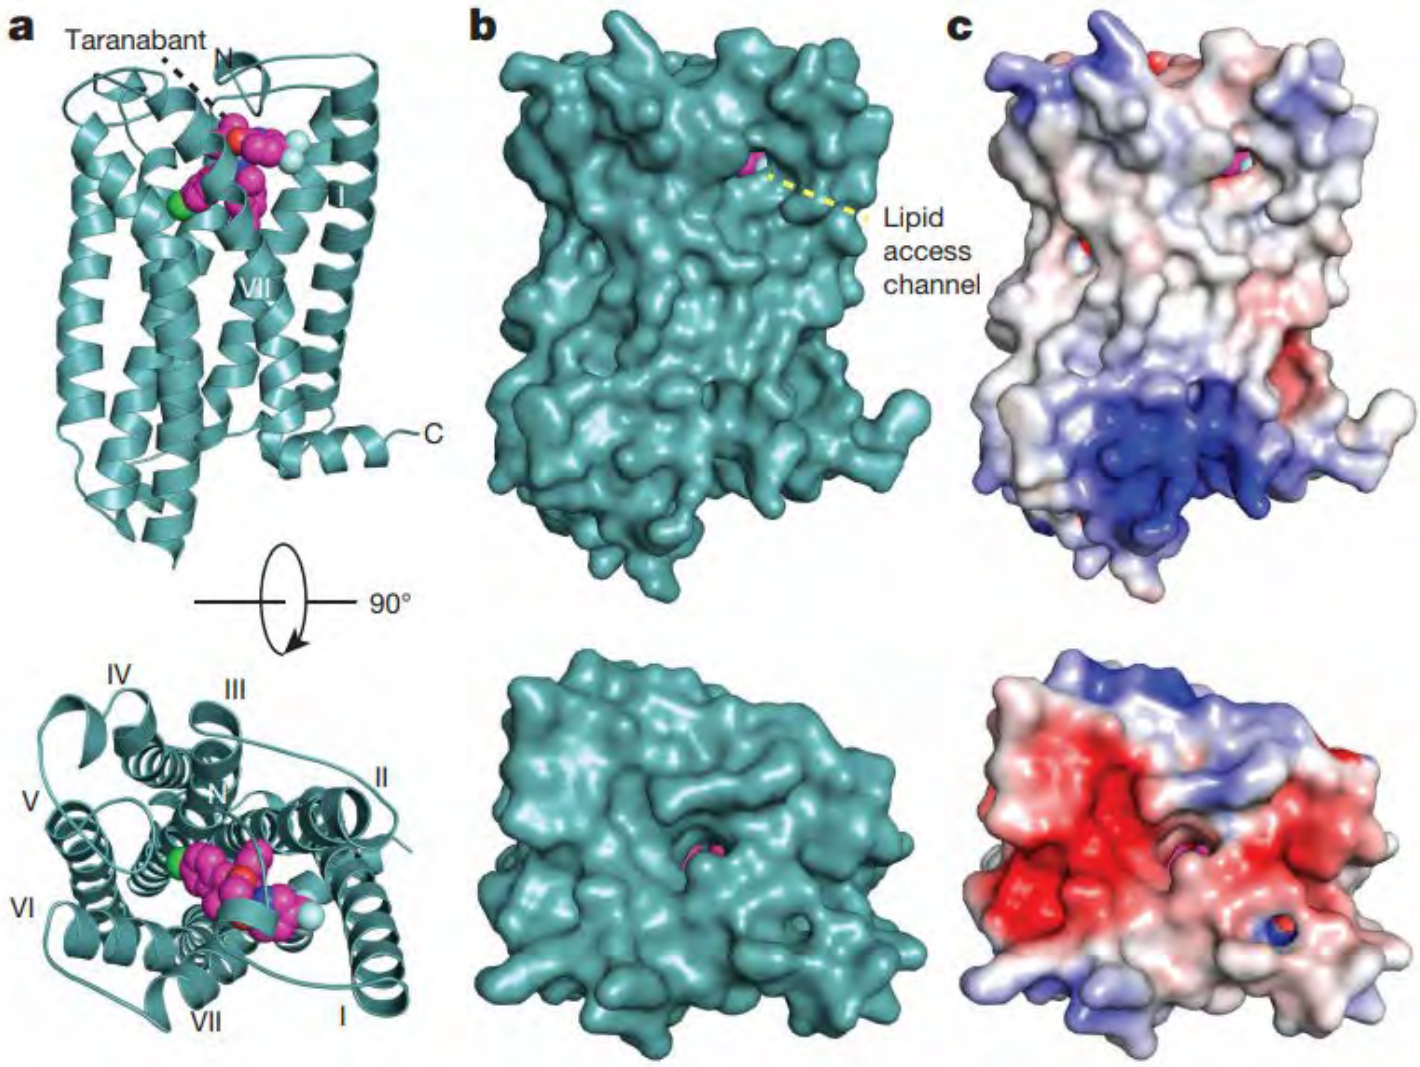

Figure 1 | Global structure of CB1 bound to taranabant. a, CB1 is

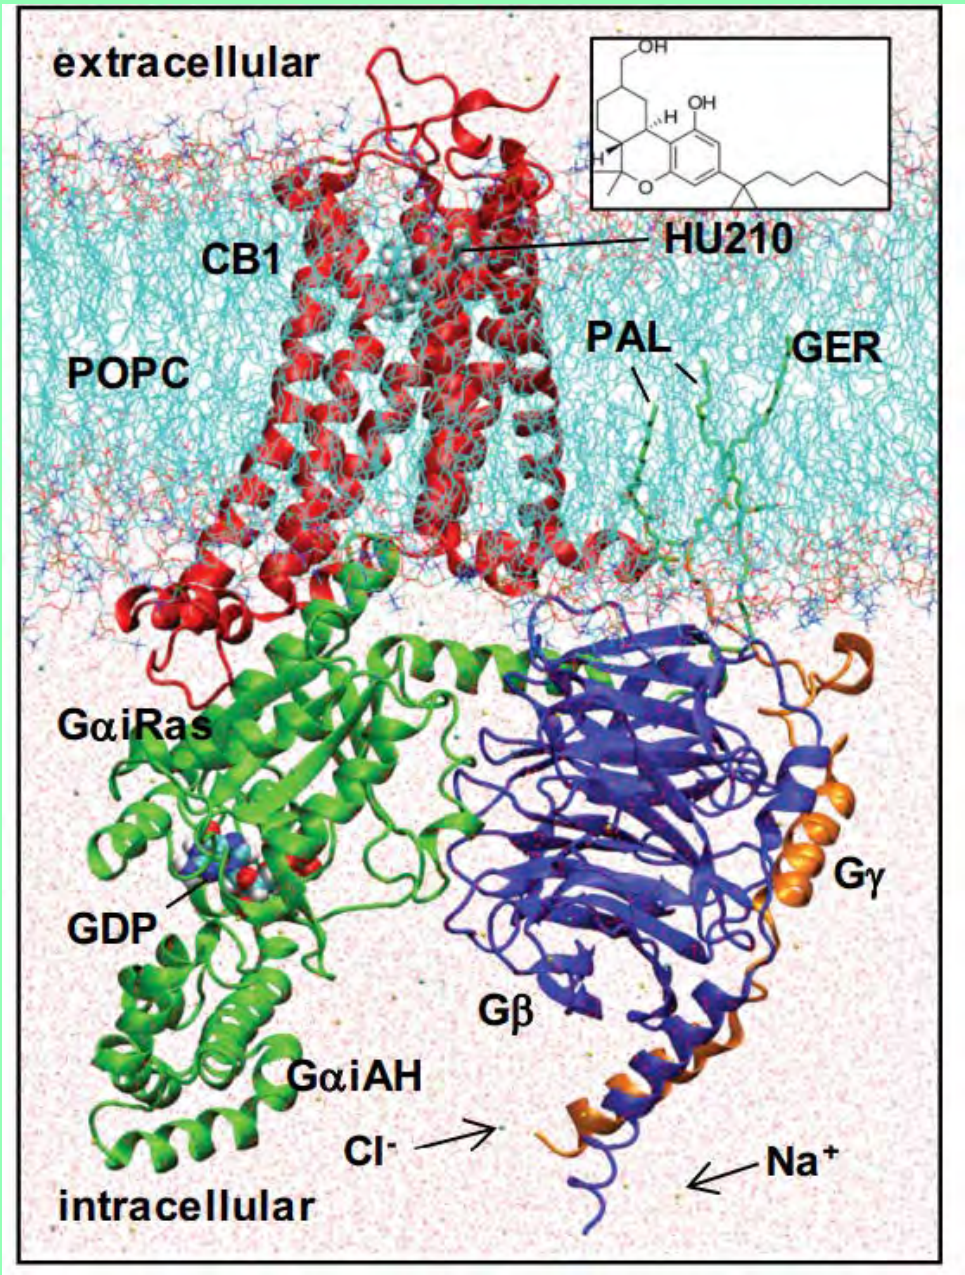
Nature. 2016 Nov 16. doi: 10.1038/nature20613. [Epub ahead of print]

High-resolution crystal structure of the human CB1 cannabinoid receptor.

Shao Z[1], Yin J[1], Chapman K[1], Grzemska M[1], Clark L[1], Wang J[2], Rosenbaum DM[1].

Key CB1 Contacts with the C-terminal Helix α_5 of $G\alpha_i$



J Biol Chem. 2013 Nov 8;288(45):32449-65. doi: 10.1074/jbc.M113.489153. Epub 2013 Oct 3.

Molecular basis of cannabinoid CB1 receptor coupling to the G protein heterotrimer Gαiβγ: identification of key CB1 contacts with the C-terminal helix α5 of Gαi.

Shim JY[1], Ahn KH, Kendall DA.

THC Docking

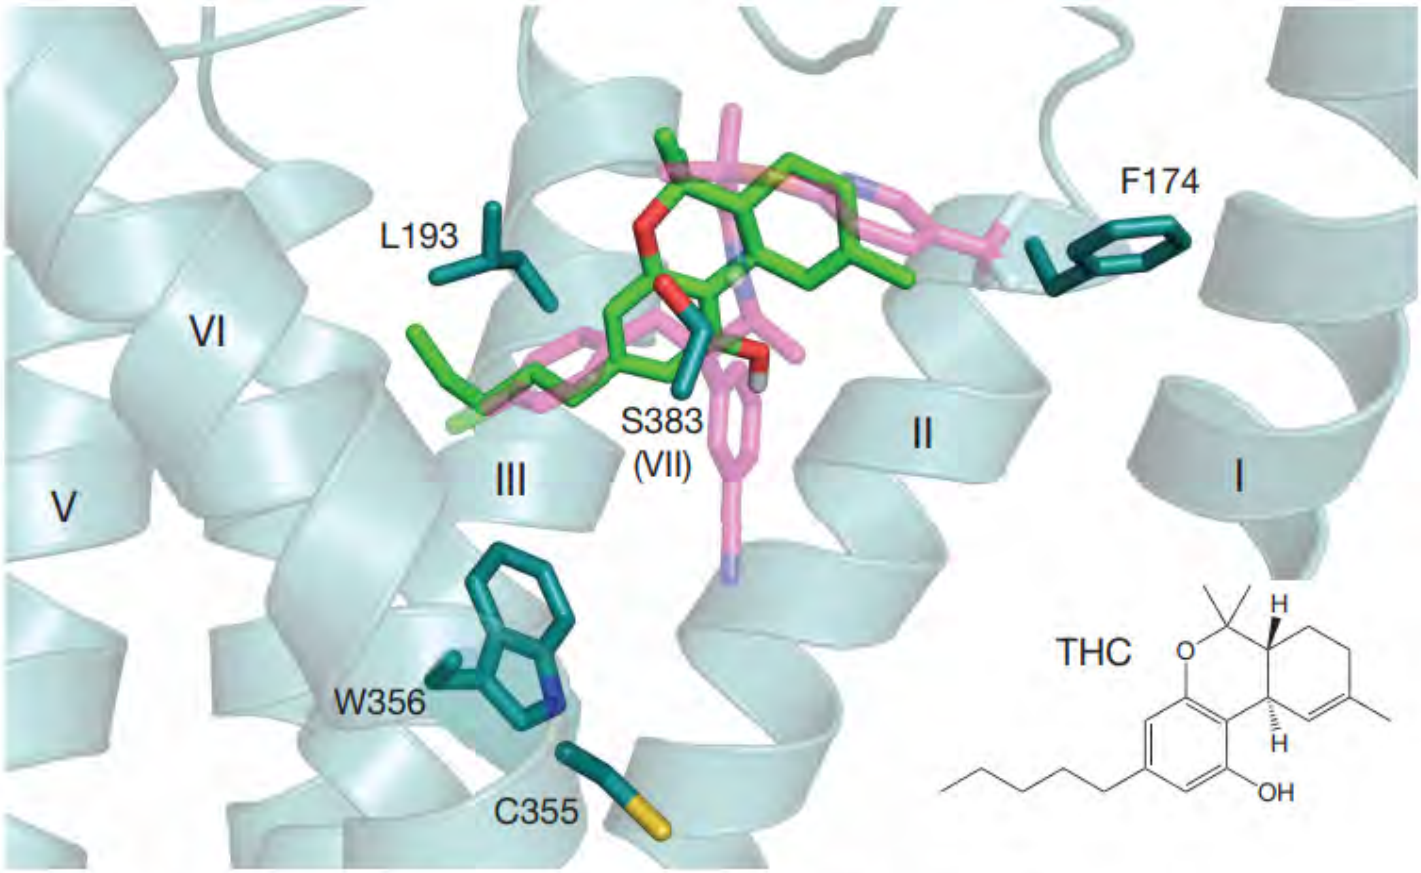


Figure 4 | Docking of rimonabant and THC to the CB1 receptor. **a**, Overlay of the crystal structure pose of taranabant (transparent magenta sticks) with the top-scoring docking pose of rimonabant shown using orange sticks (see Methods). The contact residues within 4 Å of taranabant are shown as transparent teal sticks. The 2D structure of rimonabant is shown at upper left. **b**, Top-scoring docking pose of THC is shown as light green sticks, along with taranabant (transparent magenta sticks). Selected residues important for the binding of THC and agonist activity are shown as teal sticks. TM7 cartoon is removed for clarity. The 2D structure of THC is shown on the bottom right.

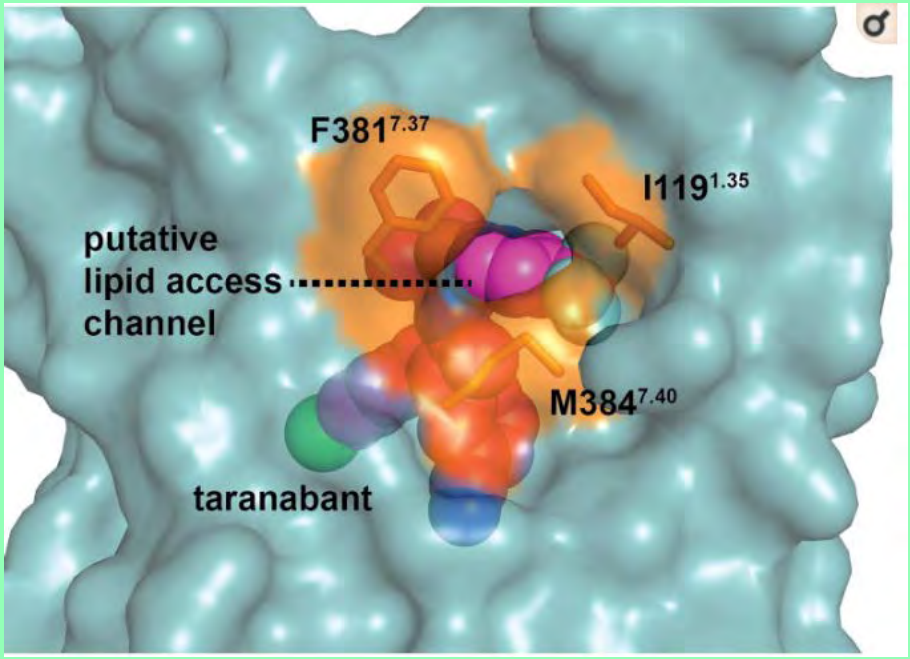
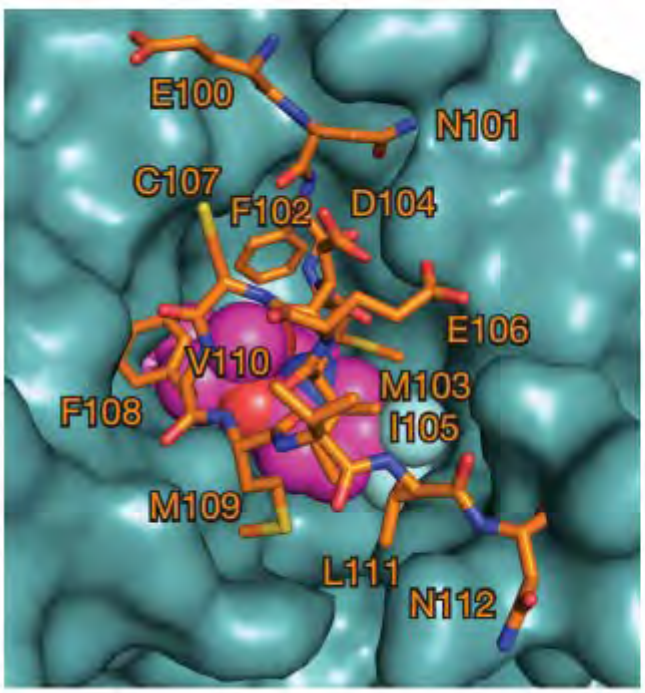
Nature. 2016 Nov 16. doi: 10.1038/nature20613. [Epub ahead of print]

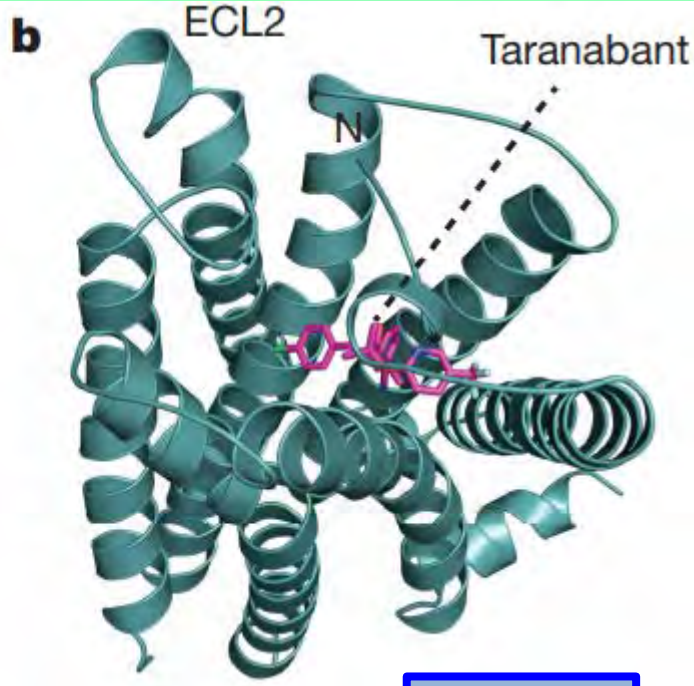
High-resolution crystal structure of the human CB1 cannabinoid receptor.

Shao Z[1], Yin J[1], Chapman K[1], Grzemska M[1], Clark L[1], Wang J[2], Rosenbaum DM[1].

Ligand Docking







284

Nature. 2016 Nov 16. doi: 10.1038/nature20613. [Epub ahead of print]

High-resolution crystal structure of the human CB1 cannabinoid receptor.

Shao Z[1], Yin J[1], Chapman K[1], Grzemska M[1], Clark L[1], Wang J[2], Rosenbaum DM[1].

287

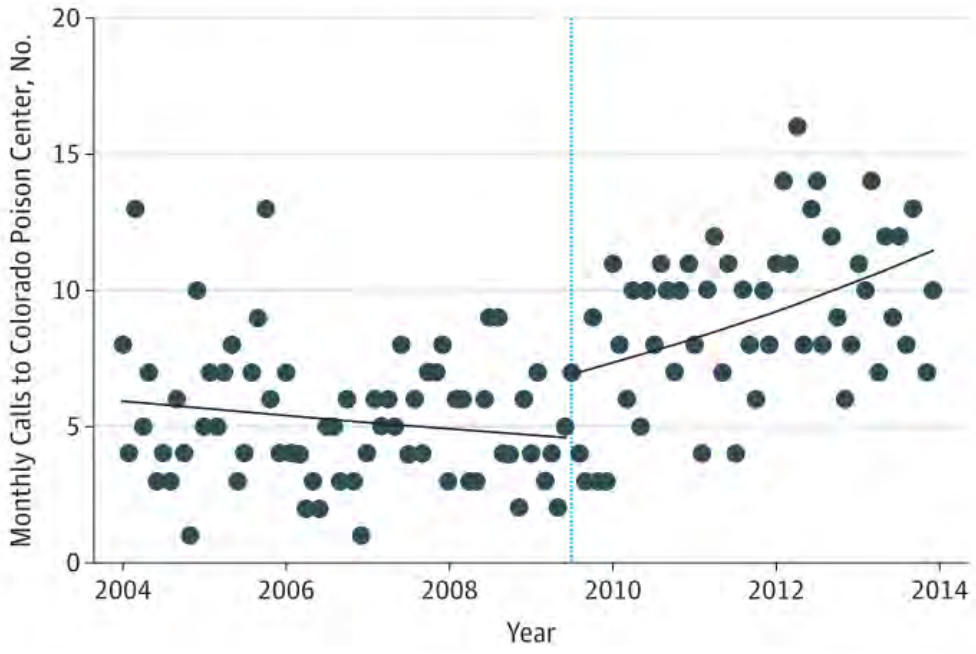
JAMA Pediatr. 2016 Sep 6;170(9):e160971. doi: 10.1001/jamapediatrics.2016.0971. Epub 2016 Sep 6.

Unintentional Pediatric Exposures to Marijuana in Colorado, 2009-2015

Wang GS[1], Le Lait MC[2], Deakyne SJ[3], Bronstein AC[2], Bajaj L[4], Roosevelt G[5].

Colorado

Figure. Calls to Colorado Poison Center



Monthly calls to the Rocky Mountain Poison and Drug Center regarding cannabis intoxication over time. The dots indicate the number of calls per month; the solid line, the best-fit trend line; the dotted line, July 2009, when the policy change was passed that allowed medical marijuana dispensaries. Adapted with permission from Davis et al.[7]

Adverse health effects of marijuana use.
Volkow ND, Compton WM, Weiss SR.
N Engl J Med. **2014** Aug 28;371(9):879. doi: 10.1056/NEJMc1407928.

Summary of Evidence

Syndrome	Dr. N. Volkow 2014-2017	Wayne Hall 2009-2016	Health Canada 2016-2017
Cannabis is Addictive	✓	✓	✓
Brain Development	✓	✓	✓
Gateway to Other Drug Use	✓	✓	
Psych.Disease - Depression, Anxiety, Psychosis	✓	✓	✓
Developmental Trajectory	✓	✓	✓
Driving / MVA	✓	✓	✓
Respiratory	✓		✓
Immunosuppression	✓	✓	
Heart Attack / Stroke / CVS Disease	✓	✓	✓
Cautions and Queries			
Cancer	?	✓	
Gestational Exposures	✓	✓	✓
Increased Potency	✓	✓	✓
ER Presentations	✓		✓

Cannabis Toxicity Effects: Generalized Systemic Toxicity

- Brain – Acute Intoxication
- Brain - Mental Illnesses
- Gateway Effect to Other Addictions
- Aborts Normal Lifetime Trajectory
- Respiratory System
- Aerodigestive Tract
- Bladder and Kidneys
- Congenital Abnormalities
- **** Reproductive Tract – Male & Female***
- **** Liver – Cirrhosis***
- **** Cancer – x10, 3 in Children***
- **** Arterial System –***
- **** Heart Attacks, Strokes***
- **** Immune System***
- **** Hormones***
- **** Genotoxicity***

i.e. Cannabis Accelerates the Ageing Process

**** = Age Defining Illnesses***

Summary

Cannabis Not Safe for:

BABIES

- Car Drivers
- Commercial Drivers - Taxis, Buses, Trains,
- Pilots of Aeroplanes
- Workers – Manual Tools, Construction, Concentration Jobs
- Children
- Adolescents
- Females of Reproductive age
- Males of Reproductive age
- Pregnancy
- Lactation
- Workers
- Older People – Mental Illness
- Immunosuppressed
- Asthmatics – 80% Population
- People with Personal History of Cancer
- People with Family History of Cancer
- People with Personal History of Mental Illness
- People with Family History of Mental Illness

- ***Accelerated Aging in Whole Population***

CAUSATION

- *Far-Reaching*
- *Public Policy &*
- *Public Health Implications*

- *For Many Generations*
